

# Storing Clang Data

For IDEs and static analysis

**Marc-André Laperle, Ericsson**

# AGENDA

1 Introductions

2 What is being done now

3 What do we want to store

4 What kind of format

5 Discussions

# Introductions

- › Marc-André Laperle
  - Software Developer at Ericsson since 2013
  - Eclipse committer for CDT (C/C++) and several other projects
  - New-ish LLVM/Clang contributor (early 2017)
  - Enthusiastic about C/C++, IDEs and tooling in general (Not a compiler expert! Yet?)

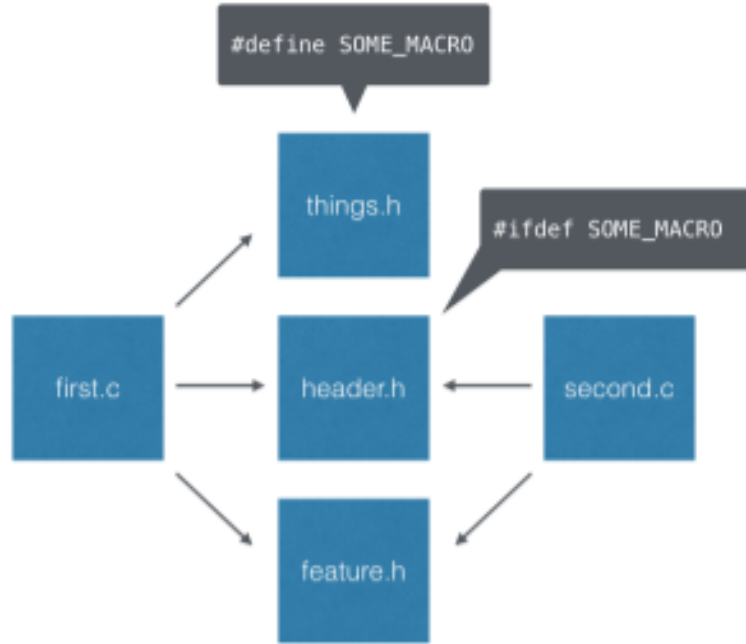

Your turn!

# What is being done now

- › Some ongoing things in Clang and Clang “extra”
  - Xcode 9’s “Index-while-building”
  - Clangd’s indexing
  - Clang Static Analyzer’s “Cross-TU” feature
  - Regular improvements to Clang/Index

# Xcode 9 “Index-while-building”

# Xcode 9 “Index-while-building”

Record  
test.cpp-190H9VS2TIBAO

```
1 class Polygon {
2     protected:
3     int NumberOfSides;
4
5     public:
6     Polygon(int NumberOfSides)
7     : NumberOfSides(NumberOfSides) {}
8
9     int getSideCount() {
10        return NumberOfSides;
11    }
12 };
13
14 class RegularPolygon : public Polygon {
15     protected:
16     int SideLength;
17
18     public:
19     RegularPolygon(int NumberOfSides, int SideLength)
20     : Polygon(NumberOfSides), SideLength(SideLength) {}
21
22     int getPerimeter() {
23        return SideLength * NumberOfSides;
24    }
25 };
26
```

The diagram illustrates the Xcode 9 indexing process. It shows a C++ source file with two classes: `Polygon` and `RegularPolygon`. The `Polygon` class is defined at line 1, and the `RegularPolygon` class is defined at line 14, inheriting from `Polygon`. The indexing process is shown as a series of boxes and arrows. The `Polygon` class is indexed as a symbol (line 1) and an occurrence (line 1). The `RegularPolygon` class is indexed as a symbol (line 14) and an occurrence (line 14). The `RegularPolygon` class is also indexed as a symbol (line 14) and an occurrence (line 14). The `RegularPolygon` class is also indexed as a symbol (line 14) and an occurrence (line 14). The `RegularPolygon` class is also indexed as a symbol (line 14) and an occurrence (line 14).

## Clangd's ClangdIndexDataStorage

- Malloc-like interface to writing in a file
- Stores raw bytes, ints, string and pointers (to other locations in the file)
- Inspired from CDT's database

# Clangd's ClangdIndexDataStorage

## File layout

0	File version
4	Linked list to free blocks of 8 bytes
8	Linked list to free blocks of 16 bytes
...	
2048	Linked list to free blocks of 4096B
2052	“User” data (Blocks)

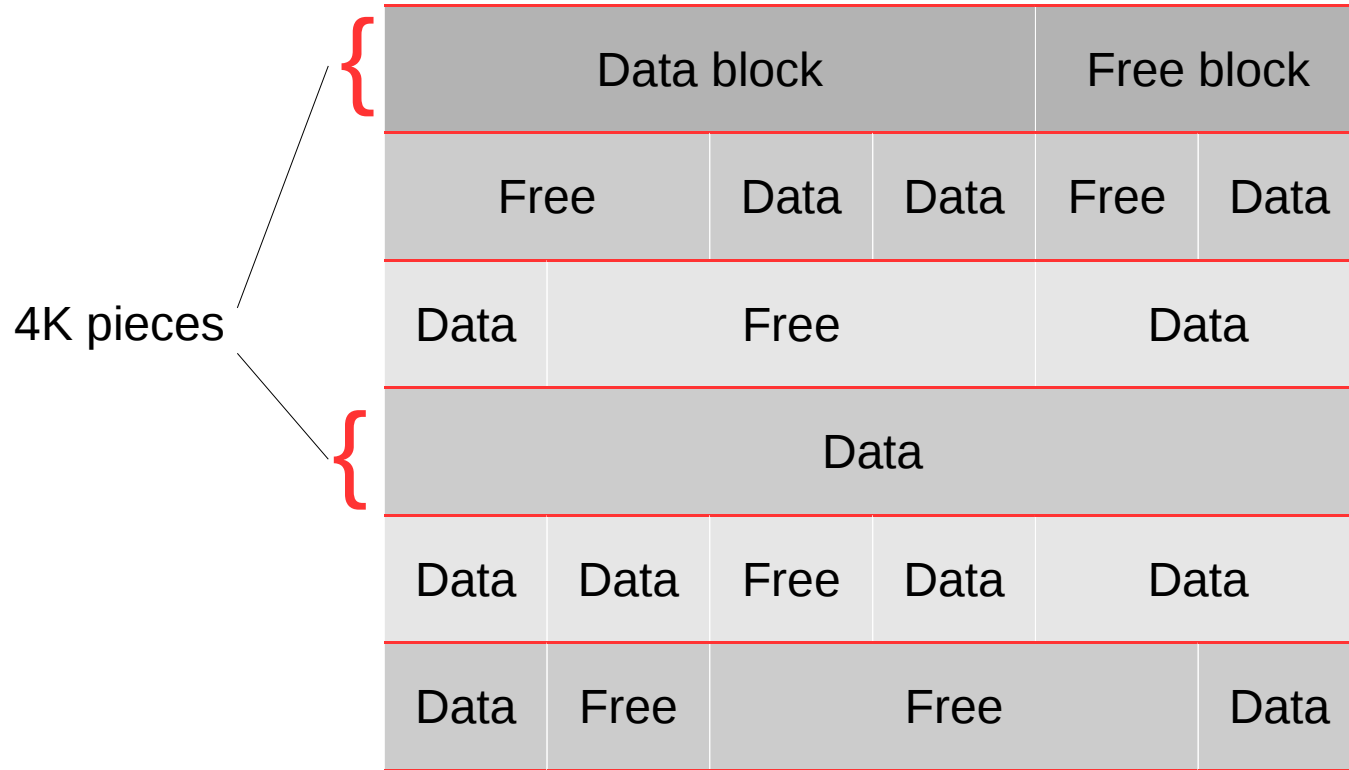

## Data block

0	Block size
2..size	Any “user” data

## Free block

0	Free block size
2	Pointer to next free block of same size
6..size	Unused (until it becomes a data block)

# Clangd's ClangdIndexDataStorage

# Clangd's BTree

- Tree with nodes containing multiple children
- Balanced
- Logarithmic insertion, search, deletion

# Clangd's BTree

- Keys are pointers to data in ClangdIndexDataStorage

# Clangd's Index Model

# Clang Static Analyzer

- When an analysis is executed, a “function to file location” mapping is generated in a file “externalFnMap.txt”
- Other stored information would be useful for performance:
  - A call graph would help incremental Cross-TU analysis
  - An “include graph” would help to know which build commands need to be re-analyzed when a file changes

# What do we want to store

- Symbols
- Occurrences (calls, references, definitions, declarations, relations)
- File dependencies
- Static analysis checker-specific information (per symbol, per function function definition, etc). I.e. make the model extensible
- Ability to not store some information (field occurrences, etc)

# What kind of format

- Xcode's libIndexStore (LLVM Bitstream)
  - Not **yet** fully upstreamed to Clang (Swift Github)
  - Format used for “Index-while-building”
  - Needs liblmbd as new dependency for mappings (or need to replace with something else)

# What kind of format

- Clangd's IndexStorage
  - Not yet upstreamed to Clang (Github)
  - Stand-alone (no new dependency)
  - Not production ready yet
  - Not created with “Index-while-building” in mind, but libIndexStore could be used as input

# What kind of format

- “Third-party” Databases
  - Some are just too big dependencies to include in Clang (MySQL, PostgreSQL, etc)
  - Smaller ones interesting: SQLite, LMDB. LMDB is quite simple and fast, could be used in combination of other formats (libIndexStore, ClangdIndexStorage)
  - How likely would a third-party database be accepted in LLVM repos?

# What kind of format

- How could other tools reuse this?
  - Link libclangIndex?
  - Link libclangDaemon
  - Launch Clangd, communicate with JSON-RPC
  - All of the above?

## Things considered for Clangd

- “Index-While-Building” feature in Xcode 9 should be reused. The index store could be used (instead of ClangdIndexStorage). Or used as input to ClangdIndexStorage.
- Move some indexing logic to Clang/Index instead of Clangd, for others to reuse
- Make indexing extensible enough so that other tools can add information to the index (Clang Static Analyzer)
- Use liblmdb, for symbol mapping, similar to Xcode
- Support for multiple “indexes” for merging different projects, libraries, etc
- Use linking information (compile\_commands.json) in order to solve the multiple definitions problem
